1 Formulation of problem

Input data

- $numNurses$: total number of nurses
- $hours$: total hour
- $minHours$: minimum hour should a single nurse be working
- $maxHours$: maximum hour can a single nurse be working
- $maxConsec$: maximum consecutive hour can a single nurse be working
- $maxPresence$: maximum hour can a single nurse be in the hospital
- $demand_h$: number of nurses required for hour h

Decision variables

- $works_{n,h}$: nurse n is working in hour h
- $working_n$: nurse n works

Math formulation

$$\boxed{Min : \sum_{n \in N} working_n} \tag{1}$$

$$\sum_{n \in N} works_{n,h} \geq demand_h \quad \forall h \in H \tag{2}$$

$$\sum_{h \in H} works_{n,h} \geq working_n * minHours \quad \forall n \in N \tag{3}$$

$$\sum_{h \in H} works_{n,h} \leq working_n * maxHours \quad \forall n \in N \tag{4}$$

$$\sum_{i \in [h, h+maxConsec]} works_{n,i} \leq maxConsec \quad \forall n \in N \quad \forall h \in [1, hours - maxConsec] \tag{5}$$

$$\sum_{i \in [h+maxPresence, hours]} works_{n,i} \leq (1 - works_{n,h}) * hours \quad \forall n \in N \quad \forall h \in [1, hours - maxPresence] \tag{6}$$

$$\sum_{i \in [h+3, hours]} works_{n,i} \leq (1 - works_{n,h} + works_{n,h+1} + works_{n,h+2}) * hours \quad \forall n \in N \quad \forall h \in [1, hours - 3] \tag{7}$$
